To get data files into R:

<u>Data on .xlsx format</u>

Two ways:

1. Write the following in your script file:

```
install.packages("readxl")    # Install the package
library(readxl)               # Load the package
data <- read_excel("the path of my document/the name of my document.xlsx")
```

Note1: you need to substitute in the path and the name of your data file for the yellow text abowe

#Note 2: How to find the path of your document?

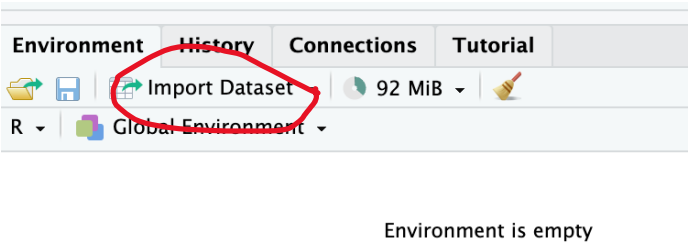
(i) On a PC you can right click any file and chose *Properties*, there you should be able to see the path for your file.

(ii) On a Mac: (1) Open a finder window (2) Choose *View -> Show Path Bar* (3) the path will show at the bottom of the finder window like this

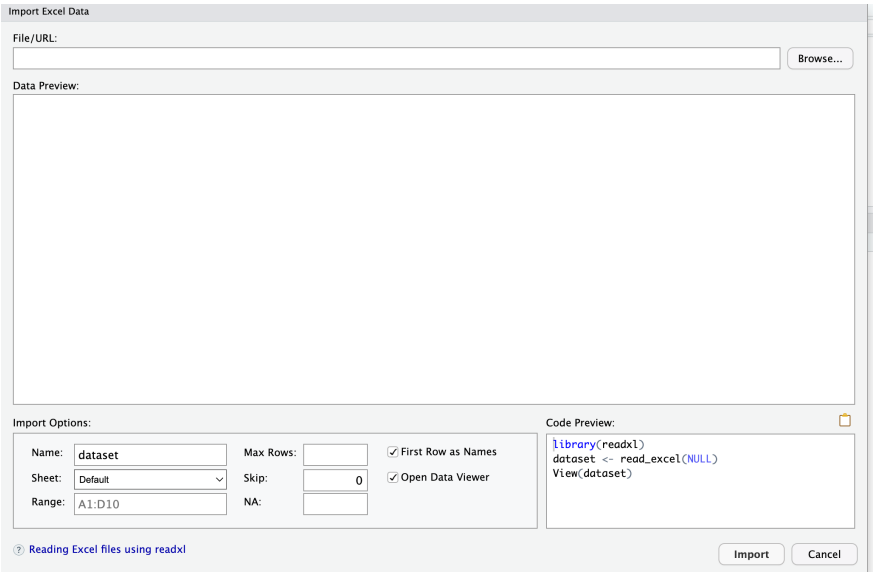
(4) If I wanted to get the path for the file sum1, I right click on sum2 in the Path Bar and choose *Copy „sum1" as Pathname* (5) You past the path into your R script.

Note3: In your code: *data <- read_excel(mydata.xlsx)* means that you are uploading your datafile mydata.xlsx, and you are renaming it *data.* If instead you write e.g. *births <- read_excel(mydata.xlsx)* your data will be called births in R.

2. In the Environment Pane chose ***Import Dataset->From Excel.*** Then yes to installing the required packages if needed.



A window like this should open:



Use **browse** to find the data file on your computer.
Note that you can change the **name** to whatever you prefer to call your data.
Then press **import.**

<u>Data on .csv format</u>

The steps are similar. Below I will highlight what is different:

1. If writing a script file:
   Reading a .csv file is part of R basic functions, so you do not need to install any package. You can simply write:
   data <- read_csv("the path of my doc/the name of my doc.csv")

   Note that R assumes that the .csv seperates the data by comms. If your file is using another delimiter, you need to specify it when reading the data. E.g. if it is a semicolon you would write:
   data <- read_csv("the path of my doc/the name of my doc.csv", sep: „;“)

2. If you you use the import function you do the same as before except you choose import dataset -> From Text (base). Use **browse** to find the data file on your computer. In the window that opens you can both change the **name** to whatever you prefer to call your data, and if needed you can also change the **seperator.** Then press **import.**
