                ("border-collapse", "collapse"), ("margin", "0 auto
        ])
    )
```

This was the code used to download the dataset to the local `data` folder:

```
(x_train_full, y_train_full), (x_test, y_test) =
keras.datasets.cifar100.load_data()

print(f"Train images: {x_train_full.shape}")
print(f"Test images:  {x_test.shape}")
```

In [3]:

```
# Load CIFAR-100 from local data folder
data_dir = "data/datasets/cifar-100-python-target/cifar-100-python"

with open(f"{data_dir}/train", "rb") as f:
    train_batch = pickle.load(f, encoding="bytes")

with open(f"{data_dir}/test", "rb") as f:
    test_batch = pickle.load(f, encoding="bytes")

x_train_full = train_batch[b"data"].reshape(-1, 3, 32, 32).transpos
y_train_full = np.array(train_batch[b"fine_labels"])

x_test = test_batch[b"data"].reshape(-1, 3, 32, 32).transpose(0, 2,
y_test = np.array(test_batch[b"fine_labels"])

print(f"Train: {x_train_full.shape}  |  Test: {x_test.shape}")
print(f"Classes: {len(np.unique(y_train_full))}")
```

```
Train: (50000, 32, 32, 3)  |  Test: (10000, 32, 32, 3)
Classes: 100
```

After loading the now local dataset, we see that the dataset contains 50,000 training images and 10,000 test images, each labeled with one of 100 fine-grained classes. To create a validation set, we performed a stratified split of the training data, reserving 10% (5,000 images) for validation while keeping the class distribution proportional across all splits. With 100 classes, a random split risks underrepresenting some classes in smaller partitions.

In [4]:
```
# 90/10 stratified validation split
x_train, x_val, y_train, y_val = train_test_split(
    x_train_full, y_train_full,
    test_size=0.1,
    random_state=42,
    stratify=y_train_full
)

print(f"Train: {x_train.shape}  |  Val: {x_val.shape}")
```

```
Train: (45000, 32, 32, 3)  |  Val: (5000, 32, 32, 3)
```

In [5]:
```
# Per-channel mean and std computed on training set only
x_train_f = x_train.astype("float32")
x_val_f   = x_val.astype("float32")
x_test_f  = x_test.astype("float32")

channel_mean = x_train_f.mean(axis=(0, 1, 2))  # shape (3,)
channel_std  = x_train_f.std(axis=(0, 1, 2))   # shape (3,)

print(f"Channel means: {channel_mean}")
print(f"Channel stds:  {channel_std}")

# Normalize all splits using training statistics
x_train_norm = (x_train_f - channel_mean) / channel_std
x_val_norm   = (x_val_f   - channel_mean) / channel_std
x_test_norm  = (x_test_f  - channel_mean) / channel_std

# Flatten for Part 1.3 (pixel-based KNN classification)
x_train_flat = x_train_norm.reshape(x_train_norm.shape[0], -1)  # (

3072)
Spatial shapes: train (45000, 32, 32, 3)  (kept for Parts 1.2 & 1.4)
```

The CIFAR-100 dataset was loaded from local pickle files, yielding 50,000 training images and 10,000 test images across 100 fine-grained classes. A

validation set was created by splitting 10% from the training data using stratified sampling, ensuring all 100 classes remain proportionally represented in both the 45,000-image training set and the 5,000-image validation set. Stratification keeps minority classes proportionally represented across both partitions.

Per-channel mean and standard deviation were computed on the training set only, then applied to normalize all three splits. Computing statistics solely on training data prevents information leakage from validation and test sets into the preprocessing step. Each normalized image was also flattened into a 3,072-dimensional vector for the pixel-based classification in Part 1.3, while the spatial 32x32x3 arrays were retained for the convolutional autoencoder (Part 1.2) and CNN (Part 1.4).

1.2 Autoencoder-Based Feature Learning

```

Figure 1: Autoencoder reconstruction loss (MSE) over training epochs

Figure 2: Autoencoder original vs reconstructed test images

A convolutional autoencoder was built following the encoder-decoder pattern from L11. The encoder consists of two convolutional blocks, each with a Conv2D layer (ReLU activation) followed by MaxPooling, progressively reducing spatial dimensions from 32x32 to 8x8 while increasing feature depth (3 -> 32 -> 64 channels). The resulting feature maps are flattened and compressed through a dense layer into a 256-dimensional latent vector.

The decoder mirrors the encoder symmetrically: a dense layer expands the latent vector back to 8x8x64, followed by two blocks of UpSampling2D and Conv2D that restore the original 32x32x3 spatial resolution. Linear activation is used in the output layer because the target images are z-score normalized (not bounded to [0, 1]).

A latent dimension of 256 was chosen as a balance between compression and information retention. The encoder compresses 4,096 features (8x8x64 flattened) down to 256, a ~16x reduction that forces the network to learn meaningful structure while keeping enough capacity for downstream classification across 100 classes.

The autoencoder was trained using MSE reconstruction loss and the Adam optimizer for 20 epochs. The trained encoder then extracts 256-dimensional latent feature vectors for the training, validation, and test sets, which will be used as an alternative feature representation for classification in Part 1.3.

1.3 Classification Using Pixel and Latent Features

In [11]:
```
# KNN on flattened pixel features (3072-dim from Part 1.1)
# Using k=5 as a reasonable default (odd number to avoid ties, not

knn_pixel = KNeighborsClassifier(n_neighbors=5)
knn_pixel.fit(x_train_flat, y_train.ravel())

pixel_val_acc  = accuracy_score(y_val.ravel(),  knn_pixel.predict(x
pixel_test_acc = accuracy_score(y_test.ravel(), knn_pixel.predict(x

print(f"KNN on pixel features  — Val accuracy: {pixel_val_acc:.4f},
```

```
KNN on pixel features  — Val accuracy: 0.1516, Test accuracy: 0.1477
```

In [12]:
```
# KNN on latent features (256-dim from Part 1.2)
# Same k=5 and default hyperparameters for fair comparison

knn_latent = KNeighborsClassifier(n_neighbors=5)
knn_latent.fit(x_train_latent, y_train.ravel())

latent_val_acc  = accuracy_score(y_val.ravel(),  knn_latent.predict
latent_test_acc = accuracy_score(y_test.ravel(), knn_latent.predict

print(f"KNN on latent features — Val accuracy: {latent_val_acc:.4f}
```

```
KNN on latent features — Val accuracy: 0.2034, Test accuracy: 0.1994
```

1	Latent (256-dim)	0.2034	0.1994

Figure 3: KNN classification accuracy comparing pixel vs latent features

A K-Nearest Neighbors classifier (k=5) was trained on two feature representations to evaluate their utility for CIFAR-100 classification. The same classifier type and hyperparameters were used for both to ensure a fair comparison.

The first KNN was trained on the 3,072-dimensional flattened pixel vectors from Part 1.1. KNN in high-dimensional spaces suffers from the curse of dimensionality (L04), where distance metrics become less discriminative as dimensions increase. This is expected to limit performance on raw pixel features.

The second KNN was trained on the 256-dimensional latent features extracted by the autoencoder from Part 1.2. By compressing the images into a learned representation, the autoencoder reduces dimensionality by ~12x while retaining structural information, giving the distance-based KNN a more meaningful feature space to work in.

Both models were evaluated on the validation and test sets. The comparison demonstrates the value of learned feature representations over raw pixel data for classification tasks.

1.4 CNN Model

In [24]:
```
# Build CNN architecture for CIFAR-100 classification
# Two convolutional blocks (2 Conv2D each) + dense head
# Following the Conv2D -> MaxPooling pattern from L12

cnn = keras.Sequential([
    # Block 1: two Conv2D layers + MaxPooling
    layers.Conv2D(32, (3, 3), activation="relu", padding="same", in
    layers.Conv2D(32, (3, 3), activation="relu", padding="same"),
    layers.MaxPooling2D((2, 2)),                # -> 16x16x32
    layers.Dropout(0.25),

    # Block 2: two Conv2D layers + MaxPooling
    layers.Conv2D(64, (3, 3), activation="relu", padding="same"),
    layers.Conv2D(64, (3, 3), activation="relu", padding="same"),
    layers.MaxPooling2D((2, 2)),                # -> 8x8x64
    layers.Dropout(0.25),

    # Classification head
    layers.Flatten(),                           # -> 4096
    layers.Dense(256, activation="relu"),
    layers.Dropout(0.5),
    layers.Dense(100, activation="softmax")     # 100 classes
])

Figure 4: CNN training curves for loss and accuracy over 30 epochs

A convolutional neural network was built following the architecture pattern from L12. The network consists of two convolutional blocks, each containing two Conv2D layers with ReLU activations followed by MaxPooling2D, for a total of four convolutional layers. Dropout (0.25) is applied after each block to reduce overfitting (L09). The feature maps are then flattened and passed through a fully connected dense layer (256 units, ReLU) with stronger dropout (0.5) before the final softmax output layer over all 100 CIFAR-100 classes.

The model was compiled with the Adam optimizer and sparse categorical cross-entropy loss, which is appropriate for integer-encoded multi-class labels. Training ran for 30 epochs on the normalized spatial images from Part 1.1, using the same 90/10 validation split for monitoring.

CNNs exploit spatial structure through local connectivity and weight sharing (L12), learning hierarchical features that flat distance-based methods like KNN cannot capture. This should give it a significant advantage over the KNN classifiers from Part 1.3.

Table 2: Classification Accuracy Across All Methods

	Method	Val Accuracy	Test Accuracy
0	KNN Pixel (3072-dim)	0.1516	0.1477
1	KNN Latent (256-dim)	0.2034	0.1994
2	CNN	0.4678	0.4657

Figure 5: Classification accuracy comparison across all methods

1.5 Results and Analysis

KNN on raw pixel features serves as the baseline, achieving 15.16% validation and 14.77% test accuracy. This is well above the 1% random chance for 100 classes, but the high dimensionality (3,072 dims) makes pixel similarity a poor proxy for semantic similarity.

Switching to the autoencoder's 256-dimensional latent features improved accuracy to 20.34% validation and 19.94% test, a roughly 5 percentage point gain. The encoder appears to retain enough structural information while discarding noise, making the compressed representations more suitable for distance-based comparison.

The CNN outperformed both by a wide margin, reaching 46.78% validation and 46.57% test accuracy. The training curves show steady improvement over 30 epochs, though a growing gap between training and validation accuracy in later epochs points to mild overfitting. Data augmentation or batch normalization could help close this gap.

Validation and test accuracy align closely across all three methods, suggesting stable generalization with no evaluation leakage. The jump from pixel KNN to latent KNN to CNN tracks what we expected: better feature representations and end-to-end optimization lead to stronger classification on a 100-class image task.
